Abstract - This paper is to review of the literature on classroom formative assessment. Several studies show firm evidence that innovations designed to strengthen the frequent feedback that students receive about their learning yield substantial learning gains. The perceptions of students and their role in self-assessment are considered alongside analysis of the strategies used by teachers and the formative strategies incorporated in such systemic approaches as mastery learning. There follows a more detailed and theoretical analysis of the nature of feedback, which provides a basis for a discussion of the development of theoretical models for formative assessment and of the prospects for the improvement of practice.

Keywords – *Online Assessment, Information and Communication Technology, Smart Coaching system.*

1. Introduction

In the recent years developments in Information and Communication Technologies (ICT) have led to a growth in the range of Internet-tools which can be used for learning and research. Some have gained wide scale acceptance (for example, the ease with which email has been taken up), others seem to find either niche applications or are less pervasive than one might have first imagined (for example, video conferencing). It provides a adequate introduction to learning technologies and their role within Higher Education. A more recent report, produced by the Association of Learning Technology, provides a useful contextualization of learning technology and technologies, an overview of the main tools and the ways in which they can be used. This study will describe the findings of an external evaluation of a project which aimed "to disseminate good practice, guidelines and models of implementation and evaluation" of one particular type of learning technology, namely computer-CAA encompasses a range of activities, including the delivery, marking and analysis of all or part of the student assessment process using standalone or networked computers and associated technologies. Previous research has shown that there are a range of motivations for implementing CAA within a course and it is often a combination of factors which result in CAA being used.

2. Literature Review

Today we live in the information age. The most important development of the information age is Computers. Huge developments in computers and computer network systems have given a birth; Internet which is the networks of networks. By means of internet reaching information has become so easy and cheap. Those main features of internet made it so popular. It has become main medium of communication, finance and education. As the scope of the World Wide Web expands to include large number of applications, it seems only natural that education becomes one of them. The opportunities for education presented by the growth of the Web should not be overlooked. The potential audience for a lecture has grown from the number of people who can fit into a classroom, to the number of people with access to Web- enabled computers. The ability to offer quality education to vast numbers of people is within our reach.

3. Existing System

The process of learning the skills of computer programming involves understanding the basic concepts. However, learning these concepts form only a small part of the true complexity of solving programming problems. Even when solving a simple programming problems will

cause emergent issues. It is difficult to teach all the logics to solve the problems. However, it is impossible to teach all the permutations of the instructions and the algorithmic structure that helps to solve the complexity problems. Hence, the users of programming each construct their own body of knowledge and understanding which expands when the user encounters and overcomes additional problems.

In modern, internet-connected learning environment, the process of learning programming can be neatly described by Papert's constructionism automated assessment and self-evaluation, where learning occurs through creatively solving problems rather than the transmission and reception of knowledge of solving the problems. This building of knowledge is most reliably achieved when the learner is experiencing the process of constructing a meaningful product rather than reproducing a rote learned series of concepts automated assessment .

To foster these processes, a teaching and learning strategy should allow a student to tackle problems in an environment where they can explore and tinker with their solutions while receiving real-time guidance. The method used to assess a user level of understanding of a topic is also an important factor to consider when designing a teaching and learning strategy. We consider two key characteristics of programming assessment: authenticity and constructive alignment. In order to be authentic, assessment of programming ability should allow the user to tinker with a solution with the benefit of feedback from the compiler or interpreter. This is a far more authentic situation than a written test, as a programmer is rarely asked to produce a working program on paper. Further, if the natural method of learning programming is through a constructionist process of experimentation and problem solving, then the assessment should also take place in a context which allows the same type of experimentation during the assessment.

The online learning and evaluating system presented in this paper addresses the approach concerns of both the learning environment and assessment of programming. As described in the coming sections, the system emulates a development environment, allowing the users to engage with the programming tasks in a setting comparable to real-world programming environment. In addition to the built-in compiler and interpreter feedback, the system also allows the instructor to devise automated guidance to help users overcome problems. The exact same system can be used for formal assessment, ensuring that the users are assessed in a realistic manner that is aligned with their learning process.

4. On-Line Assessment – Design and Tools

One of the most useful components in any course is assessment, online or not. The primary objective in testing is to determine whether students understand what the course has tried to teach them. Assessment is needed to provide evidence for evaluating student learning and assigning final course grades. Online assessment of students is today a reality in all forms of education including universities, business and industry training.

5. Structure of the Online Learning Adaptive System

We have proposed system and implementing a web application for descriptive type answers checking and its automatic assessment .Till now the systems are developed for the Automatic Evaluation of Single Sentence Descriptive Answer but by this application we are trying to provide automatic evaluation of multiple sentence descriptive answers. To increase the tolerance of the system we are going to use the Pattern Matching Technique Algorithm. We are building new system in which the descriptive examinations are also online.The system described in this work is based on the popular Moodle open-source learning platform. This platform was developed by Dougiamas, who decided to build a free and open-source learning and assessment platform focused on constructivist pedagogical principles. Moodle is licensed under the GPL written for the GNU project this protects the rights of end users to run, study, share and modify the software. This open source principle has fostered a large and active development community surrounding the Moodle project with constant active contribution to the core code-base and many community developed plug-ins that extend the capabilities of the platform in a variety of ways. Moodle itself is a PHP-based Course Management System (CMS) that can be deployed on a variety of operating systems, web servers and database systems. The full source code is available for free and is well documented which allows for end users to tinker with the system . However, easy one-click automated installation packages have also been created by companies like Bitnami to make deployment exceedingly simple . Moodle provides all the core features one would expect from a CMS, which includes robust user management, diverse content management tools, scheduling tools, a variety of assessment tools, messaging, a grade management system, integration of plug-ins and support for learning module standards like SCORM .This open community has led to the development of many useful plug-ins for Moodle, and the system described in this paper is based on a Moodle

plug-in called the Virtual Programming Lab (VPL) developed and maintained by Rodríguez-del-Pino.

5.1 Virtual Programming Lab(VPL) Plug-In

The VPL plug-in is a system designed to present and assess programming assignments through the Moodle platform. The plug-in consists of three main elements. The first is the main plug-in module that runs on the Moodle server; the second is an editor component that allows for the editing of source code in the browser. Finally, there is the jail server that acts as a sandbox environment that executes the student's code. The main plug-in module of VPL, which runs on the Moodle server, manages the descriptions of the assignments, the marking scripts and protocols, the grading process, scheduling settings, access restrictions, similarity checks and controls how a student's code will be executed on the jail server. The editor is an integral part of the VPL plugin and provides a capable in-browser editor environment that supports syntax highlighting for the various supported languages and multiple file support through tabs. The editor allows students to edit the assignment source code, provides the interface to the development environment to receive feedback from compilers or interpreters and allows the student to submit assignments for automatic assessment, feedback and grading. The final element of the VPL system is the jail servers. These are the servers that the VPL plug-in transmits a student's code to for execution. These servers are where the tool chains for the various supported languages are installed. As of the writing of this report, VPL can currently execute 27 languages with varying levels of support for syntax highlighting, debugging and graphical user interfaces. Executing student's code is a risky endeavor for a server as students are prone to producing bad code that can inadvertently compromise an operating system through memory leaks, infinite loops or system calls. Some students are also bound to test the limits of an execution environment and attempt to execute malicious code on the server. In this way, the VPL system can control the maximum allowed system resources that a given student program can use and protect the jail system from erroneous or malicious code during execution.

The VPL system supports using multiple jail servers for a single Moodle environment and manages the load balancing between these servers when many students are using the system simultaneously. When a student submits a program for execution it is transmitted to the jail server along with the execution scripts created by the instructor. These scripts are then used to execute the code using the appropriate compiler or interpreter. The output of the program, compiler or interpreter is then sent back to the

student with a standard command-line interface. VPL has recently added support for graphical output from programs in addition to the command line interface. This is achieved by using the VNC remote access software that is built into most modern Linux distributions. This interface then streams a basic windows environment back to the student's browser allowing them to interact with the graphical elements of the environment they are currently engaged with. The VPL system also includes a source code similarity measurement system which is used to analyse the submissions for a given assignment and report back on their relative similarities using an easy to navigate interface. This tool makes it possible to determine which students submitted plagiarized code with a minimal time investment. For use of VPL in strict testing environments, the plug-in includes the standard Moodle activity security features that provide the ability to control access to an activity using a password and to limit access by network addresses. This allows an instructor to limit access to an activity to a specified set of computers, such as those in the lab where the assessment is being conducted. VPL can also disable the ability to copy and paste text in the editor, which ensures that a student was the author of an activity.

5.2 Automated Assessment using VPL

The real power of VPL as a tool for teaching and assessing programming assignments is in its automated execution and assessment capabilities. VPL runs a student's code using a BASH script to prepare the source files, compile the code (or send it to the relevant interpreter) and then execute the code. The standard output stream of this process is then provided to the student via a console window in their browser where a student can interact with the running program. When a program is being assessed, a different BASH script is used to compile. This assessment script will then provide automated input to the program and evaluate its behavior for grading purposes. Out of the box VPL includes default run, evaluation and debugging scripts for all the supported languages. A standard format for defining basic evaluation test cases is also provided.

Using the built-in evaluation scripts involves defining a series of test cases where the input provided to the program is defined along with the expected output that the program should print to the standard output stream. Grading conditions are provided for each test case. VPL includes a C++ grading program which takes in the specified test cases and uses them to evaluate a student's submission and automatically grade the submission. While this capability provides an easy way to quickly produce automatically assessed programming assignments it is very limited. Input can only be provided via the standard input stream and the output is naively assessed as a single output numeric or

direct string comparison. This means that for a student to be graded as correct their program's output must conform exactly to the specified solution output with no extra spaces or new-line characters. This can often lead to confusion: defining the exact form of the required output can be challenging, and students will often not understand the formatting issues created by spaces and new-line characters which are difficult to spot in a text console. Unfortunately, the execution script side of VPL is not very well documented and the only real source of information provided comes in the form of the default run and evaluation BASH scripts provided with the VPL source code. The first thing the custom evaluation does is load the file which contains the flags produced by the validation process. If any of the three validation conditions have been detected the appropriate message is given to the student and they receive a zero grade. Next, the script will run the student's submission. In order to confirm that the random data set is indeed random, another phase of validation is performed. The data set is recorded to file. The student's submission is run a second time and the new data set is compared to first data set. If the data set is truly random these arrays' will be different. If they are not, then it indicates that the student has manipulated the contents of the dataset. They receive an appropriate error message and grade. The script then calculates the model sorting signature for the random data set. If the student's submission matches this sorting signature, then they receive full marks. If they sorted the algorithm using a different algorithm but the array is sorted correctly, they will receive half credit. Otherwise they have not met the question specifications and will receive a zero grade.

6. Application of Learning System to Goals

This section will discuss how the learning system supports the pedagogical philosophy described in Section II. The first major benefit of the system is that it lives in the cloud and is accessible from any decently sized device that can run a modern web browser. This means that students have access to a code editor and the relevant tool chains from any internet connected computer without needing to install any specialized software. This has greatly increased the access to these technologies, especially for students who have limited resources at their disposal. The system was built to support a constructionist pedagogical philosophy and does so far better than traditional assessment of programming. The automated assessment tools can provide real-time feedback from the compiler/interpreter and built-in clues and guidance from the instructor, meaning that students can work at their own pace to solve programming problems but are given appropriate feedback every step of the way. An instructor can write scripts that detect

common mistakes and provide clues on how to address these common errors to the student. In this way, the student can work at their own pace and work towards a solution on their own terms and when they have solved a problem the system will inform them of the fact. This is important because often students are not able to identify when a problem is adequately solved and by having the system automatically inform them they get the satisfaction of having solved a problem on their own without having to be told days later that they were successful through a manually graded assignment. The system also provides an appealing alternative to traditional partial credit grading. Paper-based assessments are inherently submitted once, and the submitted work must be evaluated as is. With the system presented here, students can be expected to correct small mistakes based on the compiler or instructor feedback and produce (and test) a working program. This expectation of a working solution fosters learning to develop an understanding rather than incentivizing memorization to earn partial credit. Note that the system does not preclude partial credit: an instructor can build assessments that assess levels of completion of a programming task, or allow for common mistakes (as in the sort example). This flexibility caters for all levels of student performance but still ensures that each student is producing at least basic complete programs. The automation also means that it becomes possible to very quickly and consistently assess the level of capability that a student has demonstrated through their performance. If deemed appropriate, grading schemes can also be adapted to include number of incorrect submissions or compilation attempts, code efficiency, submission time, and more; the combination of the course management system and scripting environment is remarkably flexible. The system also provides a trove of data about student participation and progress, keeping track of almost every action a student takes. This data can definitively answer questions about student participation and progress which might traditionally rely on self-reporting from students.

7. Conclusion

Day by day technology is enhancing and with developments in technology, education system is shifting from in class settings to online environment. Assessment system cannot stand out of that trend. Assessment must be parallel with teaching. Today it is out of debate that whether Online assessment should be used. The main issue in online assessment is how it can be more effective, valid, reliable and secure. Based on the results indicated in previous section those conclusions have been reached in terms of online assessment.

1. Students should be familiar with the assessment tool, in specific they should be familiar with web browsers.

2. Students should be trained to prevent problems caused by lack of system use.
 3. In general students regard online assessment tool as appropriate for assessment.
 4. Students wanted to take the same form of the exam for the other courses as well.
 5. In order to prevent problems might be caused an electricity cut there should be an UPS (Uninterrupted Power Supply) connected to computers used for online assessment.
 6. Students should be informed about the security features of the system.
 7. The online assessment system should be secure and authentic
 8. Server must be powerful enough to support the online assessment tool without any problem.
 9. Computers used for online assessment should be running properly.
 10. Students regard developed online assessment tool as effective and easy to use.
 11. Immediate feedback makes student progress better.
 12. Immediate feedback has a positive impact on learning process.
 13. Students should be able to learn in exams as well.
 14. Assessment style should be parallel with the teaching style.
 15. In the exam Students should be able to take notes
 16. In the exam students should be able to see their initial answers.
 17. Questions should be appeared page by page instead of showing all the questions in one page and number of questions appeared in a page should be arranged easily.
- Students should be able to see (if they want) left time for exam.
